

Security risk assessment report

Part 1: Select up to three hardening tools and methods to implement

First hardening tools need to implement:

Create strong firewall to check for incoming and outgoing traffic

Second hardening tool:

Properly set up MFA/Multi Factor Authentication

Third hardening tool:

Create strong password policy

Part 2: Explain your recommendations

After creating a strong firewall, and maintenance, it blocks all unwanted traffic, and only allows legitimate traffic, and useful against DoS/DDoS attacks where flooded packets were sent all together.

For MFA authentication, it helps the user to make sure the person is legitimate and requires an extra layer of security, and reduces the chance of brute force attack to login to any account. MFA authentication discourages users from sharing passwords, since there is always extra authentication required aside from password.

For creating a strong password policy, users are always suggested to make long passwords, something not easily guessed by malicious actors, and in some cases, not even able to brute force attack, and leads to accounts unable to login for malicious actors. This will eventually stop the malicious actors from infiltrating the network.
